Sectoral Performance, Risk, and Trading Opportunity Analysis of NIFTY-50 Stocks Using Python and Tableau

Cover Page

Group Name: Fino_50 (C-1)

Team Members:

- Aryan Verma - Exploratory Data Analysis, KPI framework, chart outputs
- Devaansh Kathuria - Extraction, ETL, cleaning pipeline, processed data
- Birajit Saikia - Final Tableau asset pack, report, presentation, QA
- Abhey Dua - Statistical analysis, risk scoring, segmentation
- Atharv Paharia - Dataset sourcing, repository setup, problem framing

Project Sector:

Finance / Stock Market Analytics

Institute:

Newton School of Technology

GitHub Repository:

Hopper__C-1_Fino_50

Tableau Public Dashboard URL:

Pending publication. This must be replaced with the final Tableau Public URL before final submission.

Submission Date:

April 28, 2026

Submission Note:

Unless explicitly stated otherwise, all numeric values in this report are computed from the versioned project outputs in outputs/tables/ and the final Tableau extracts in data/processed/tableau_stock_level.csv, data/processed/tableau_sector_level.csv, data/processed/tableau_yearly_trends.csv, data/processed/tableau_risk_segments.csv, and data/processed/tableau_recommendation_view.csv.

Executive Summary

This project converts raw daily market data for NIFTY-linked stocks into a reproducible analytics workflow for sector comparison, risk evaluation, liquidity screening, and dashboard-ready decision support. The committed dataset covers 2000-01-03 to 2021-04-30, contains 235,192 cleaned daily rows, tracks 49 stable company-file stock keys, and spans 13 mapped sectors.

The final output combines Python ETL, KPI construction, EDA, statistical testing, and a Tableau-ready asset pack. The strongest broad-based market expansion in the sample occurred in 2003 with 50.54% equal-weighted cumulative return, while 2008 was the deepest yearly drawdown at -41.59%. At the stock level, TCS leads both annualized return (21.15%) and opportunity score (91.73). At the sector level, CEMENT & CEMENT PRODUCTS leads annualized return (16.69%) and opportunity score (82.69), while VEDL has the highest composite risk score (98.98).

The final recommendation layer separates names into Buy, Watch, Trade Candidate, and Avoid groups using transparent rule-based segments instead of opaque black-box labels. This keeps the project academically defensible and more practical for viva discussion.

Sector And Business Context

Indian equity markets generate a large volume of historical stock-level trading data, but portfolio decisions still require structure. Investors need to compare not only raw returns, but also volatility, drawdown, liquidity, delivery participation, and sector resilience. A clean dashboard and report are useful only if the underlying calculations are reproducible and the filters reflect real business questions.

In this project, the business context is investor decision support rather than algorithmic trading. The intended user is a portfolio analyst, research student, or retail-investor-focused reviewer who wants to narrow the opportunity set quickly while keeping risk visible.

Problem Statement And Objectives

Problem Statement

Raw NIFTY historical data is not directly decision-ready. Without structured cleaning and derived metrics, it is difficult to determine which sectors and stocks combine return quality, manageable downside, liquidity, and investor conviction.

Objectives

- preserve raw data and build a reproducible ETL pipeline
- create a cleaned and standardized analytical dataset
- define stock-level and sector-level KPIs
- perform EDA for regime, sector, and liquidity insights
- apply statistical methods for risk and comparison questions
- export Tableau-ready files that support an investor-oriented dashboard
- assemble final report, presentation, and submission QA assets

Data Description

Source

- Primary dataset: Kaggle NIFTY-50 Stock Market Data (2000-2021) by Rohan Rao
- Local raw path: data/raw/nifty-dataset/
- Metadata path: data/raw/nifty-dataset/stock_metadata.csv

Coverage

- Raw combined file rows: 235,192
- Cleaned rows: 235,192
- Raw columns in NIFTY50_all.csv: 15
- Cleaned analytical columns: 35
- Stable file-level stock keys used for KPI aggregation: 49
- Historical row-level symbols observed: 65
- Sector count: 13

Core Variables

- price variables: previous close, open, high, low, last, close, VWAP
- activity variables: volume, turnover, trades
- participation variables: deliverable volume, deliverable percent
- metadata variables: company name, industry, ISIN
- derived analytical fields: returns, spreads, VWAP gap, turnover in crore, delivery ratio, flags, and date components

Data Limitations And Biases

- The dataset is historical and cannot prove future market behavior.
- Historical NIFTY membership changes create more row-level symbols than the current NIFTY-50 count.
- Missing trades and delivery fields affect the certainty of participation-related conclusions.
- Sector counts are uneven, so sector-level comparisons should be read as decision-support evidence rather than universal sector laws.

Data Cleaning And ETL Methodology

The ETL workflow is implemented in scripts/etl_pipeline.py and documented in docs/cleaning_log.md. The pipeline detects stock files, attaches metadata, standardizes column names to snake_case, converts numeric fields safely, validates OHLC consistency, and engineers derived features.

Key cleaning decisions:

- per-stock files are preferred over NIFTY50_all.csv to avoid double counting
- no exact duplicate rows were removed because none were found
- price fields required no final manual imputation after symbol-wise fill checks

- turnover was rescaled by 100000 because the committed raw field was consistently inflated relative to VWAP * Volume
- missing trading-activity fields were kept visible through flags instead of hidden
- outlier returns were flagged, not deleted, so downstream analysis could exclude them transparently through analysis_return

Important ETL evidence from versioned outputs:

- missing trades rows: 114,848
- missing deliverable_percent rows: 16,077
- missing deliverable_volume rows: 16,077
- invalid OHLC rows: 0
- outlier return rows flagged: 12,680

KPI And Metric Framework

The KPI layer is documented in docs/kpi_framework.md and exported through outputs/tables/stock_kpis.csv, sector_kpis.csv, yearly_market_summary.csv, and covid_period_summary.csv.

The most important KPIs are:

- cumulative return
- annualized return
- volatility
- average daily return
- max drawdown
- risk-adjusted return
- average volume
- average turnover in crore
- average delivery percent
- liquidity score
- investor confidence score
- opportunity score

Why the framework matters:

- return alone can over-reward speculative names
- volatility alone can misclassify slow wealth destroyers
- liquidity matters for execution but not as a direct quality signal
- delivery participation adds context for conviction
- the opportunity score provides a single investor-screening field without hiding the component logic

EDA

EDA was performed through notebooks/03_eda.ipynb and scripts/eda_analysis.py. The work focused on market regimes, sector comparisons, liquidity behavior, delivery participation, and COVID-era stress and recovery.

Key EDA outputs:

- outputs/charts/yearly_market_trend.png
- outputs/charts/top_10_stocks_return.png
- outputs/charts/sector_return_comparison.png
- outputs/charts/sector_volatility_comparison.png
- outputs/charts/volume_turnover_trend.png
- outputs/charts/delivery_percent_trend.png
- outputs/charts/risk_return_scatter.png
- outputs/charts/covid_crash_recovery.png

The EDA stage established the core narrative that the market behaves differently across regimes, sectors, and participation styles. It also showed that turnover and liquidity need to be interpreted together with delivery strength and risk, not in isolation.

Statistical Analysis

Statistical analysis was completed in notebooks/04_statistical_analysis.ipynb and scripts/statistical_analysis.py. The analysis added correlation checks, hypothesis testing, downside-risk metrics, transparent stock segmentation, and moving-average trend context.

Methods Used

- Pearson and Spearman correlation analysis
- independent two-sample t-test for high-delivery vs low-delivery stock returns
- Kruskal-Wallis test for sector return distribution differences
- downside-volatility, historical VaR, and historical CVaR calculation
- rule-based segmentation into five stock groups
- 20-day and 60-day moving-average regime checks

Core Statistical Results

- daily_return vs volume: weak positive correlation, statistically significant, economically weak
- daily_return vs turnover_cr: weak positive correlation, statistically significant, economically weak
- daily_return vs deliverable_percent: weak negative correlation, statistically significant, economically weak
- volatility_percent vs annualized_return_percent: weak negative relationship, not statistically significant
- liquidity_score vs risk_adjusted_return: weak negative relationship, not statistically significant
- high-delivery vs low-delivery stock return test: $p = 0.4856$, so no strong evidence of a return advantage
- sector return difference test: $p = 0.0379$, so sector dispersion is statistically detectable

This supports a cautious interpretation: sector selection matters, downside risk matters, but delivery intensity and raw activity variables are weak stand-alone return signals.

Tableau Dashboard Design

The final dashboard is specified in tableau/dashboard_blueprint.md and uses these exported files:

- data/processed/tableau_stock_level.csv
- data/processed/tableau_sector_level.csv
- data/processed/tableau_yearly_trends.csv
- data/processed/tableau_risk_segments.csv
- data/processed/tableau_recommendation_view.csv

The Tableau layer is built to answer six investor questions:

1. What is the market regime and how has it changed over time?
2. Which sectors offered the strongest performance-risk trade-off?
3. Which stocks combine return quality, liquidity, and conviction?
4. Which names are risky enough to require caution or tactical positioning?
5. Which sectors recovered best from the COVID crash?
6. Which stocks should be tagged as Buy, Watch, Trade Candidate, or Avoid?

The final-load validation output in outputs/tables/final_load_validation.csv confirms:

- all five Tableau exports were generated
- duplicate key rows are 0 across all exported datasets
- no unusable index columns were written
- KPI availability is 100% for four of the five files
- the trend file has expected early-history gaps in rolling averages and some delivery coverage gaps, leaving KPI availability at 99.5%

Dashboard status at report draft time:

The Tableau-ready data pack and dashboard blueprint are complete, but the final Tableau workbook, screenshots, .twbx export, and Tableau Public URL must still be completed in Tableau before submission. The final PDF should be regenerated after those assets are added.

Required interactive filters:

Year, sector or industry, stock symbol, risk bucket, segment, and date range.

Screenshot plan:

Screenshots should be stored in tableau/screenshots/ and inserted into this section after the workbook is built. Minimum screenshots should include the executive KPI view, market trend view, sector comparison view, stock opportunity view, COVID crash/recovery view, and recommendation view.

Key Insights

1. The equal-weighted market had its best yearly expansion in 2003 with 50.54% cumulative return and its weakest in 2008 with -41.59%.

2. The dataset covers 49 stable stock keys and 13 sectors, which is enough to compare opportunity, risk, and liquidity without relying on fabricated entities.

3. TCS is the strongest all-around stock in the current KPI framework with 21.15% annualized return and 91.73 opportunity score.

4. CEMENT & CEMENT PRODUCTS is the strongest sector on both annualized return (16.69%) and opportunity score (82.69).

5. VEDL is the highest-risk stock in the universe with a 98.98 risk score and a -92.42% max drawdown.

6. The 2020 COVID crash phase delivered -17.25% cumulative return, but the recovery phase rebounded 37.42%, showing a short, severe drawdown followed by strong reversal.

7. Recovery behavior was uneven across sectors; cement, pharma, and IT show stronger recovery narratives than weaker opportunity sectors such as services, telecom, and media.

8. Liquidity is necessary for execution but insufficient for investment quality. Highly liquid names do not automatically rank well on opportunity score or long-run return.

9. Delivery intensity alone does not explain stock-level return differences in this sample because the high-delivery vs low-delivery test was not significant.

10. Sector differences are meaningful enough to justify sector-aware dashboard views because the Kruskal-Wallis test rejected equal return distributions at the 5% level.

11. The sample ended on 2021-04-30 with a market Downtrend signal because the 20-day moving average (366.95) was below the 60-day moving average (368.84).

12. The recommendation layer narrows the universe to 8 Buy names, 11 Watch names, 18 Trade Candidate names, and 12 Avoid names, which creates an actionable final story for Tableau.

Recommendations

1. Use the Buy bucket as the core long-horizon shortlist because it is anchored in the Stable Compounders segment and supported by stronger opportunity scores.

2. Use Trade Candidate names for tactical monitoring only, especially when they come from High Growth High Risk or liquidity-led segments.

3. Keep Watch names visible for lower-volatility positioning, especially under weaker market trend signals.

4. Deprioritize Avoid names in the default dashboard ranking because their return quality and risk profile do not support strong allocation arguments.

5. Lead the sector story with cement, IT, pharma, automobile, and financial services rather than weaker opportunity sectors such as services, telecom, and media.

Impact Estimation

This capstone does not claim realized portfolio returns, but it can estimate decision-support impact.

- The recommendation layer reduces the active review set from 49 stocks to 8 core Buy names for a first-pass shortlist. That is an 83.7% reduction in screening load.
- The sector layer reduces the attention set from 13 sectors to the top 3 or 5 sectors depending on the view, which lowers dashboard complexity while keeping the strongest comparative stories visible.
- The final Tableau pack consolidates the project into 5 versioned CSV files, making dashboard construction faster and more reproducible than rebuilding metrics inside Tableau.
- The validation file surfaces data quality openly, reducing the risk of silent spreadsheet mistakes during final dashboard assembly.

Limitations

- The dataset is historical and backward-looking.
- The stock universe may still contain survivorship and constituent-change effects.
- Some missing trades and deliverable fields remain in the source data and are intentionally not fabricated.
- Statistical significance in long time-series data should not be confused with causality.
- Sector counts are uneven, so some sector comparisons are more stable than others.
- The recommendation layer is rule-based decision support, not live investment advice.

Future Scope

- add benchmark comparison against NIFTY index or macro indicators
- test rolling-window robustness for opportunity and risk scores
- enrich the recommendation layer with valuation or earnings data
- publish the final Tableau dashboard with narrative annotations and parameter actions
- extend the project to include scenario analysis and portfolio simulation

Conclusion

The project now reaches the final integration stage with reproducible ETL, documented KPIs, EDA evidence, statistical analysis, and a Tableau-ready asset pack. The strongest project story is not simply that some stocks went up more than others, but that risk, liquidity, delivery strength, sector behavior, and crash recovery can be combined into a clearer investor-screening framework. The final deliverables are positioned for submission as long as the team completes the final manual packaging steps for Tableau .twbx, screenshots, and PDF exports.

Appendix

Appendix A: Key Output Artifacts

- cleaned dataset: data/processed/nifty50_cleaned.csv
- stock KPIs: outputs/tables/stock_kpis.csv
- sector KPIs: outputs/tables/sector_kpis.csv
- yearly summary: outputs/tables/yearly_market_summary.csv
- risk summary: outputs/tables/risk_summary.csv
- stock segments: outputs/tables/stock_segments.csv
- recommendation evidence: outputs/tables/recommendation_evidence.csv
- final Tableau pack:

data/processed/tableau_stock_level.csv, data/processed/tableau_sector_level.csv, data/processed/tableau_yearly_trends.csv, data/processed/tableau_risk_segments.csv, and data/processed/tableau_recommendation_view.csv

- final load validation: outputs/tables/final_load_validation.csv

Appendix B: Data Dictionary Summary

Field Group	Representative Columns	Business Use
Price fields	prev_close, open, high, low, close, vwap	return, volatility, spread, and trade-quality analysis
Activity fields	volume, turnover, trades, turnover_cr	liquidity and market-depth analysis
Delivery fields	deliverable_volume, deliverable_percent, delivery_ratio	participation and holding-conviction proxy
Metadata fields	source_symbol, company_name, industry, isin_code	stock and sector grouping
Quality flags	missing_price_flag, missing_volume_flag, invalid_ohlc_flag, outlier_return_flag	transparent ETL validation and analysis filtering
KPI fields	annualized_return_percent, volatility_percent, max_drawdown_percent,...	stock and sector decision support

Full field definitions are maintained in docs/data_dictionary.md.

Appendix C: Cleaning Log Summary

- Raw stock files used: 50
- Combined raw file detected but not stacked: 1

- Cleaned rows: 235,192
- Date range: 2000-01-03 to 2021-04-30
- Missing trades rows: 114,848
- Missing deliverable_percent rows: 16,077
- Invalid OHLC rows: 0
- Outlier return rows flagged: 12,680
- Turnover scale factor applied: 100000

The full cleaning log is maintained in docs/cleaning_log.md.

Appendix D: Notebook And Script References

Project Stage	Notebook	Supporting Script
Extraction	notebooks/01_extraction.ipynb	scripts/etl_pipeline.py
Cleaning	notebooks/02_cleaning.ipynb	scripts/etl_pipeline.py
EDA and KPIs	notebooks/03_eda.ipynb	scripts/eda_analysis.py
Statistical analysis	notebooks/04_statistical_analysis.ipynb	scripts/statistical_analysis.py
Final Tableau load	notebooks/05_final_load_prep.ipynb	final-load notebook code

Appendix E: Chart And Table Outputs

Core chart outputs are stored in outputs/charts/, including yearly trend, sector return, sector volatility, delivery trend, risk-return scatter, COVID crash/recovery, correlation heatmap, and segmentation visuals.

Core table outputs are stored in outputs/tables/, including cleaning summary, stock KPIs, sector KPIs, yearly market summary, COVID period summary, statistical test results, risk summary, stock segments, recommendation evidence, and final load validation.

Appendix F: Tableau Submission Note

The dashboard must be exported and submitted in .twbx format only. The Tableau Public link should be stored in tableau/dashboard_links.md after publication and should match the same final packaged workbook.

Appendix G: Contribution Matrix

Team Member	Dataset & Sourcing	ETL & Cleaning	EDA & Analysis	Statistical Analysis	Tableau Dashboard	Report Writing	PPT & Viva
Aryan Verma	Support	Review	Lead: KPIs, EDA charts, insight memo	Support	Chart support	Support	Support
Devaansh Kathuria	Support	Lead: ETL pipeline, cleaning notebook, processed data	Support	Support	Data support	Support	Support
Birajit Saikia	Review	Final integration QA	Final integration QA	Final integration QA	Lead: Tableau CSV pack, blueprint, dashboard links	Lead: final report assembly	Lead: presentation outline and viva prep
Abhey Dua	Support	Review	Support	Lead: tests, risk scoring, segmentation, recommendations	Statistical evidence support	Support	Support
Atharv Paharia	Lead: sourcing, repository setup, initial framing	Support	Support	Support	Support	Early documentation	Support

Contribution evidence:

- Git history shows visible commits from all five members.
- git shortlog -sne --all shows 6 commits each for Aryan Verma, Devaansh Kathuria, Birajit Saikia, Abhey Dua, and Atharv Paharia in the audited local repository history.
- The matrix above should still be checked against GitHub Insights and any pull request evidence before final form submission.

Final note:

This matrix should be cross-checked one last time against the final commit history before form submission.
